14th of November 2018

Structure

- 1 Motivation
- 2 Data background
- 3 Method of Estimation
- 4 Comparison of Load Duration Distribution
- 5 Conclusion

What is our aim?

Wind 4.0

Motivation

- On-shore auction-market announcement of wind farms
 - Increasing cost pressure

$$\min \text{ LCoE} = \frac{\text{Investment} + \sum_{t=1}^{\text{life time}} \frac{\text{Annual Costs}}{(1+i)^t}}{\sum_{t=1}^{\text{life time}} \frac{\text{AEP}}{(1+i)^t}}$$

- Monitoring features
 - Structural Health Monitoring
 - Particle counter
 - Vibration sensors
 - Accelerometer

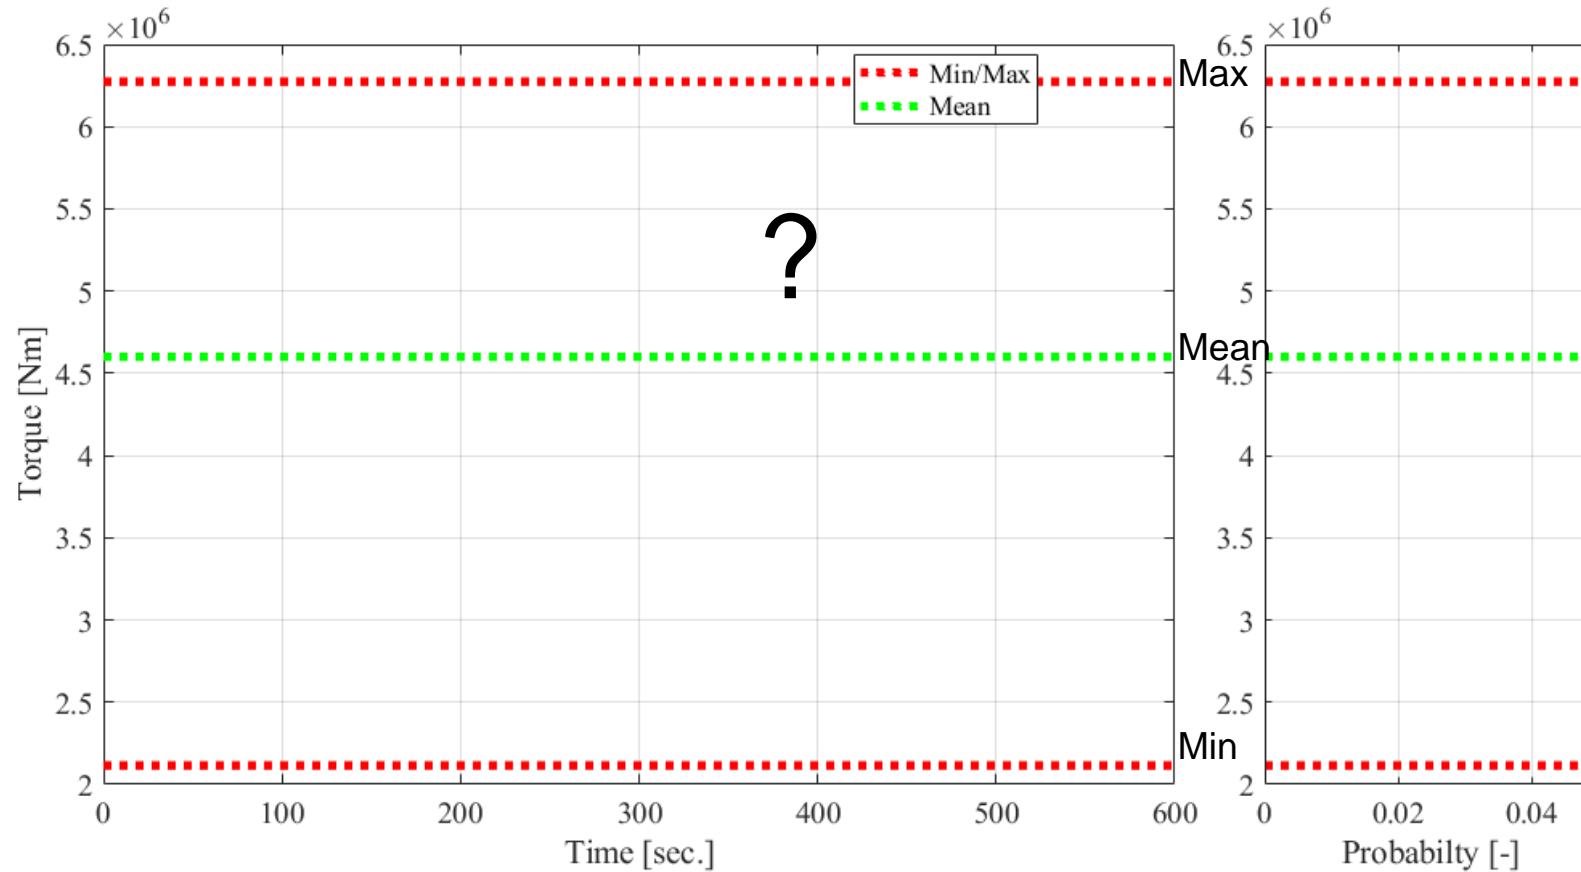

Motivation

- Every wind turbine equipped with SCADA-System
 - 200-1000 signals
 - 10 min Mean, Min and Max value
 - Integrated monitoring system
 - Recording of individual past
- ➔ Direct rating of utilization of each wind turbine
- ➔ Identification of fault behavior and trends

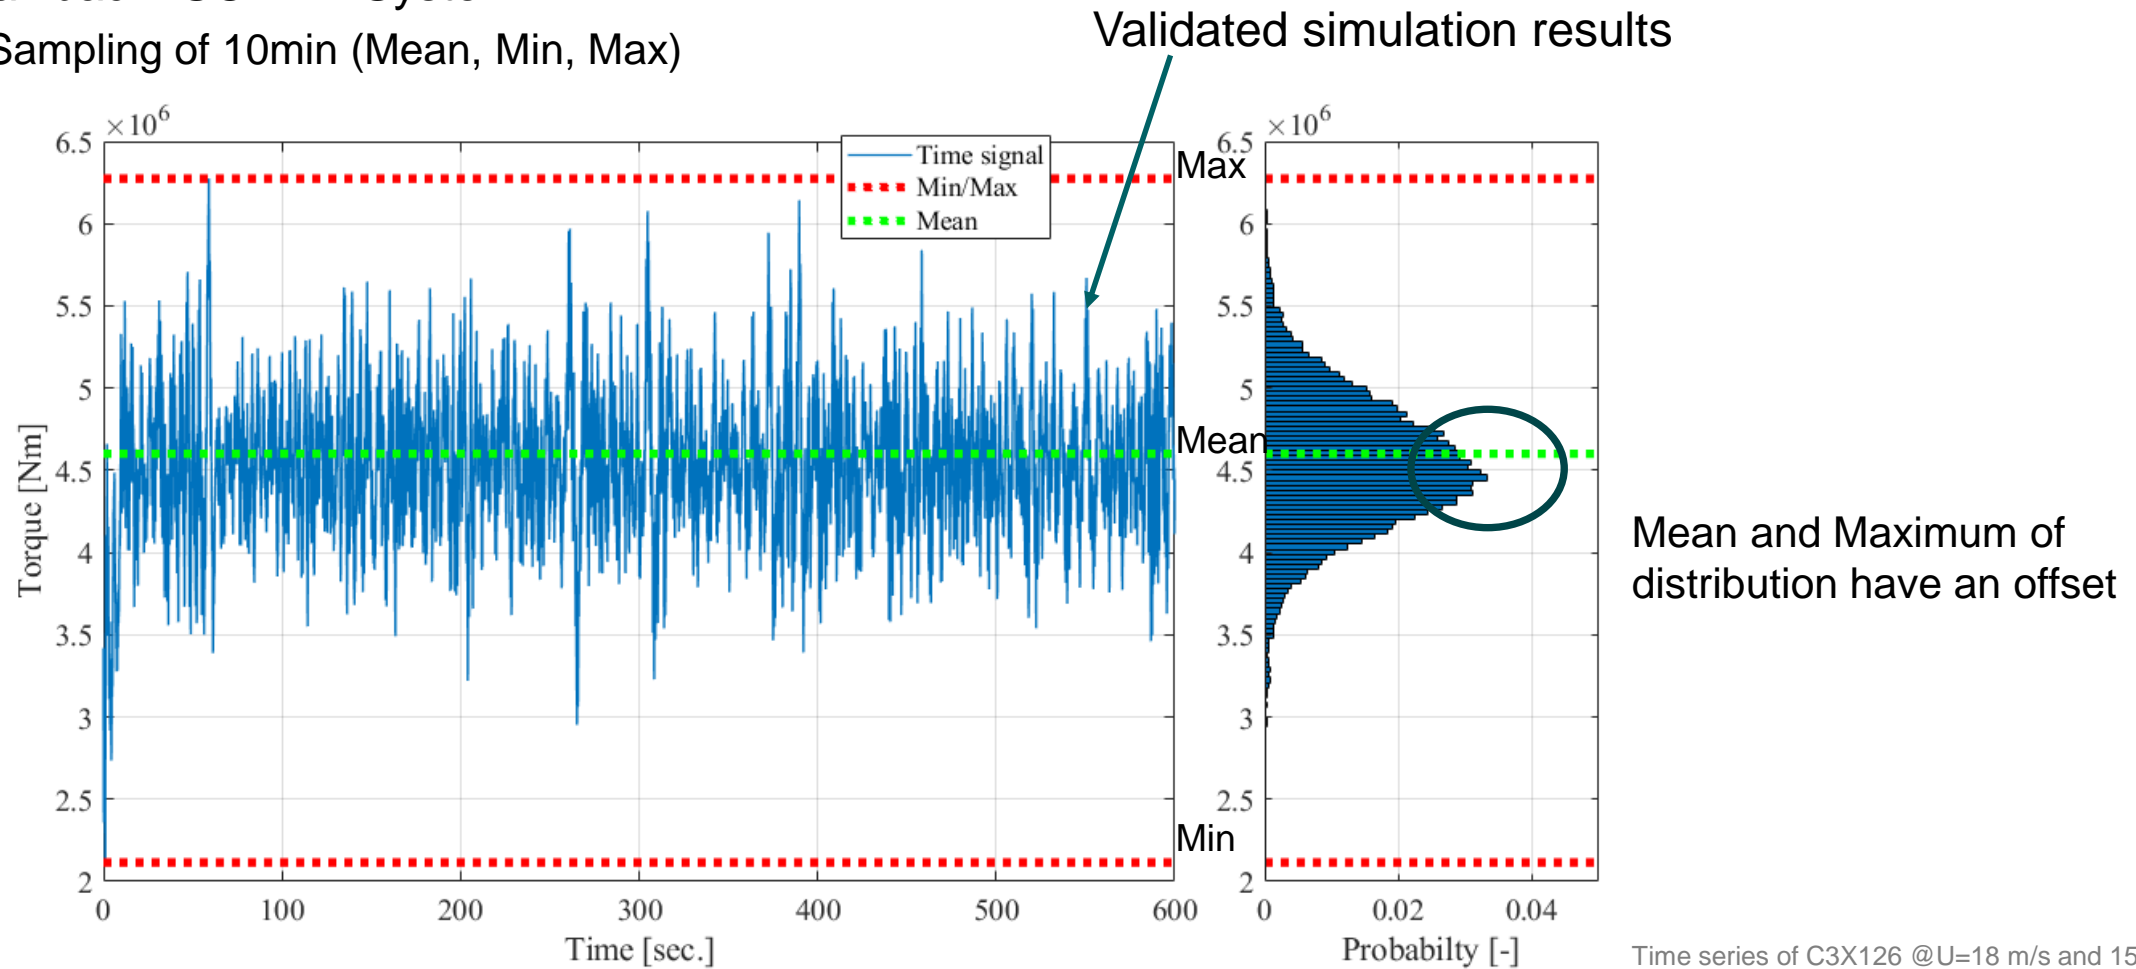

SCADA System setup

- Drawback: SCADA-System
 - Sampling of 10min (Mean, Min, Max)

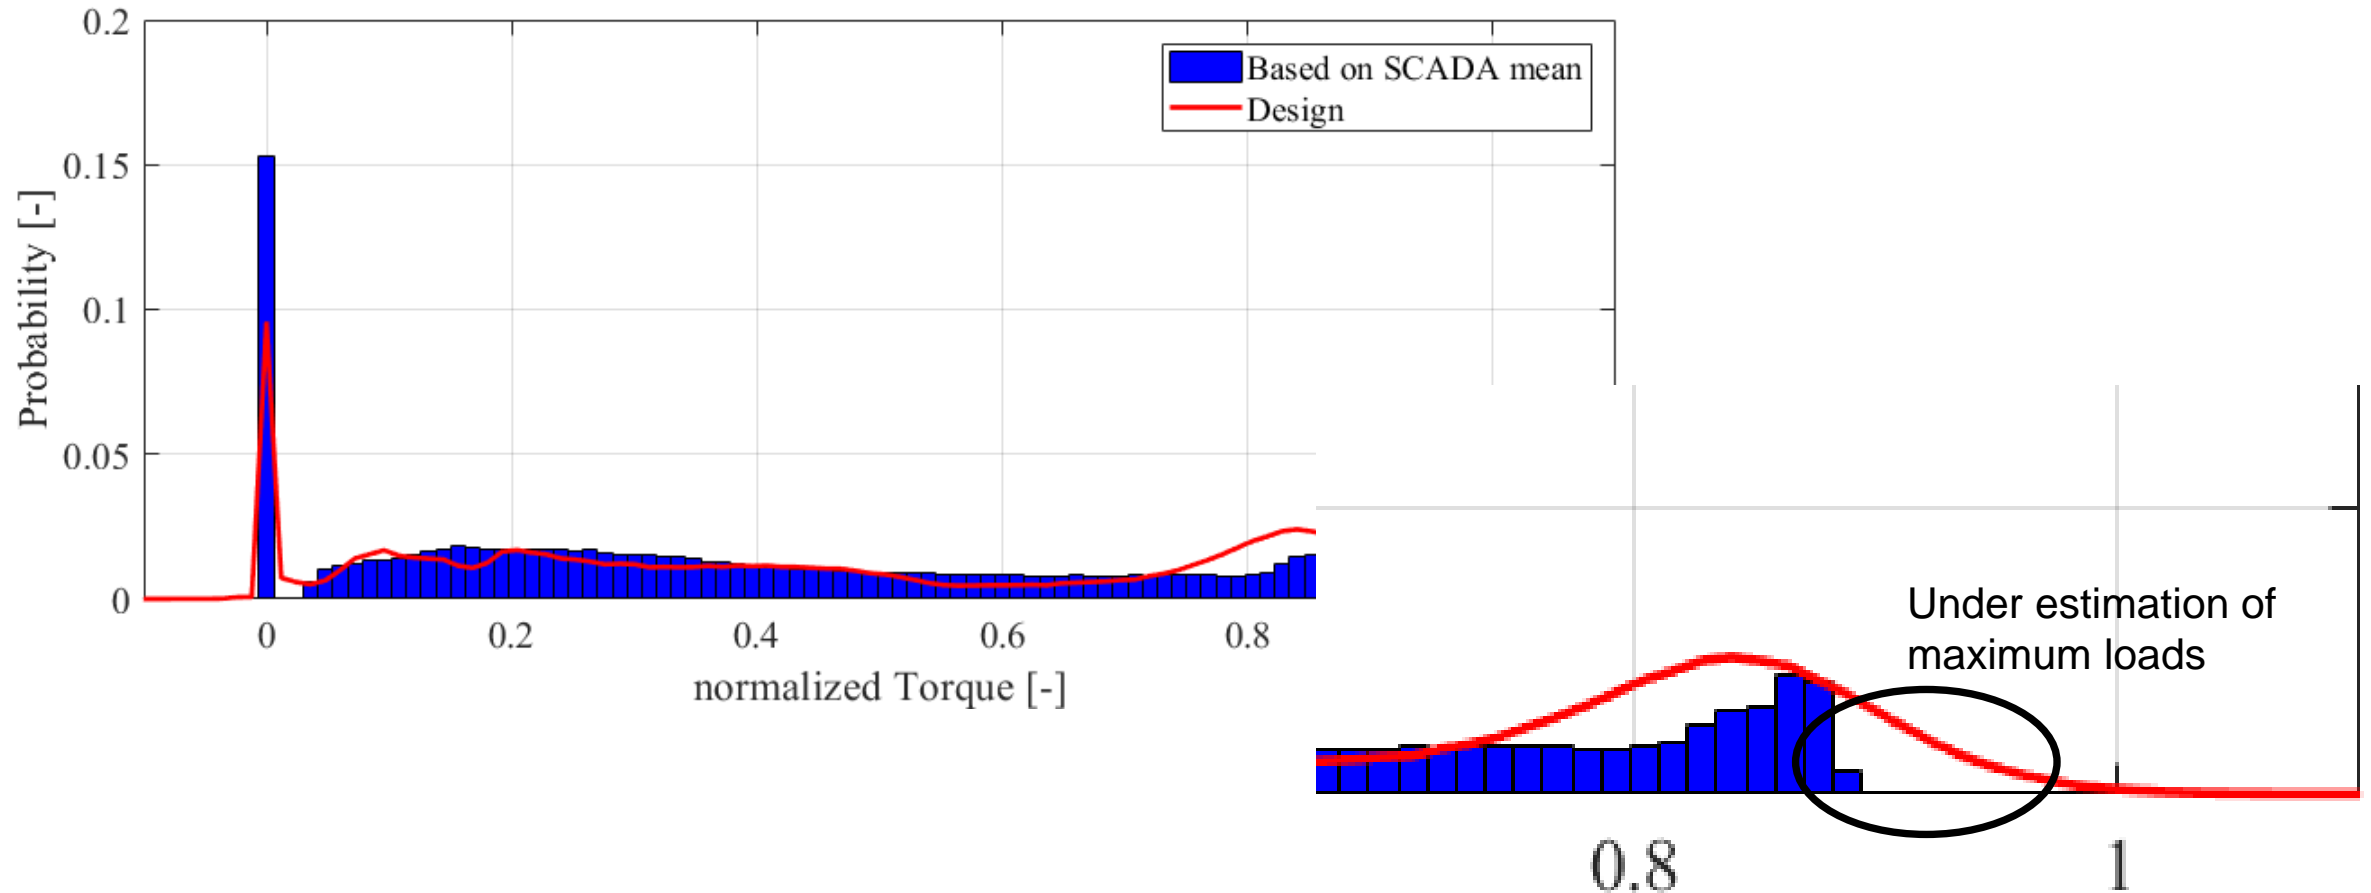

SCADA System setup

- Drawback: SCADA-System
 - Sampling of 10min (Mean, Min, Max)

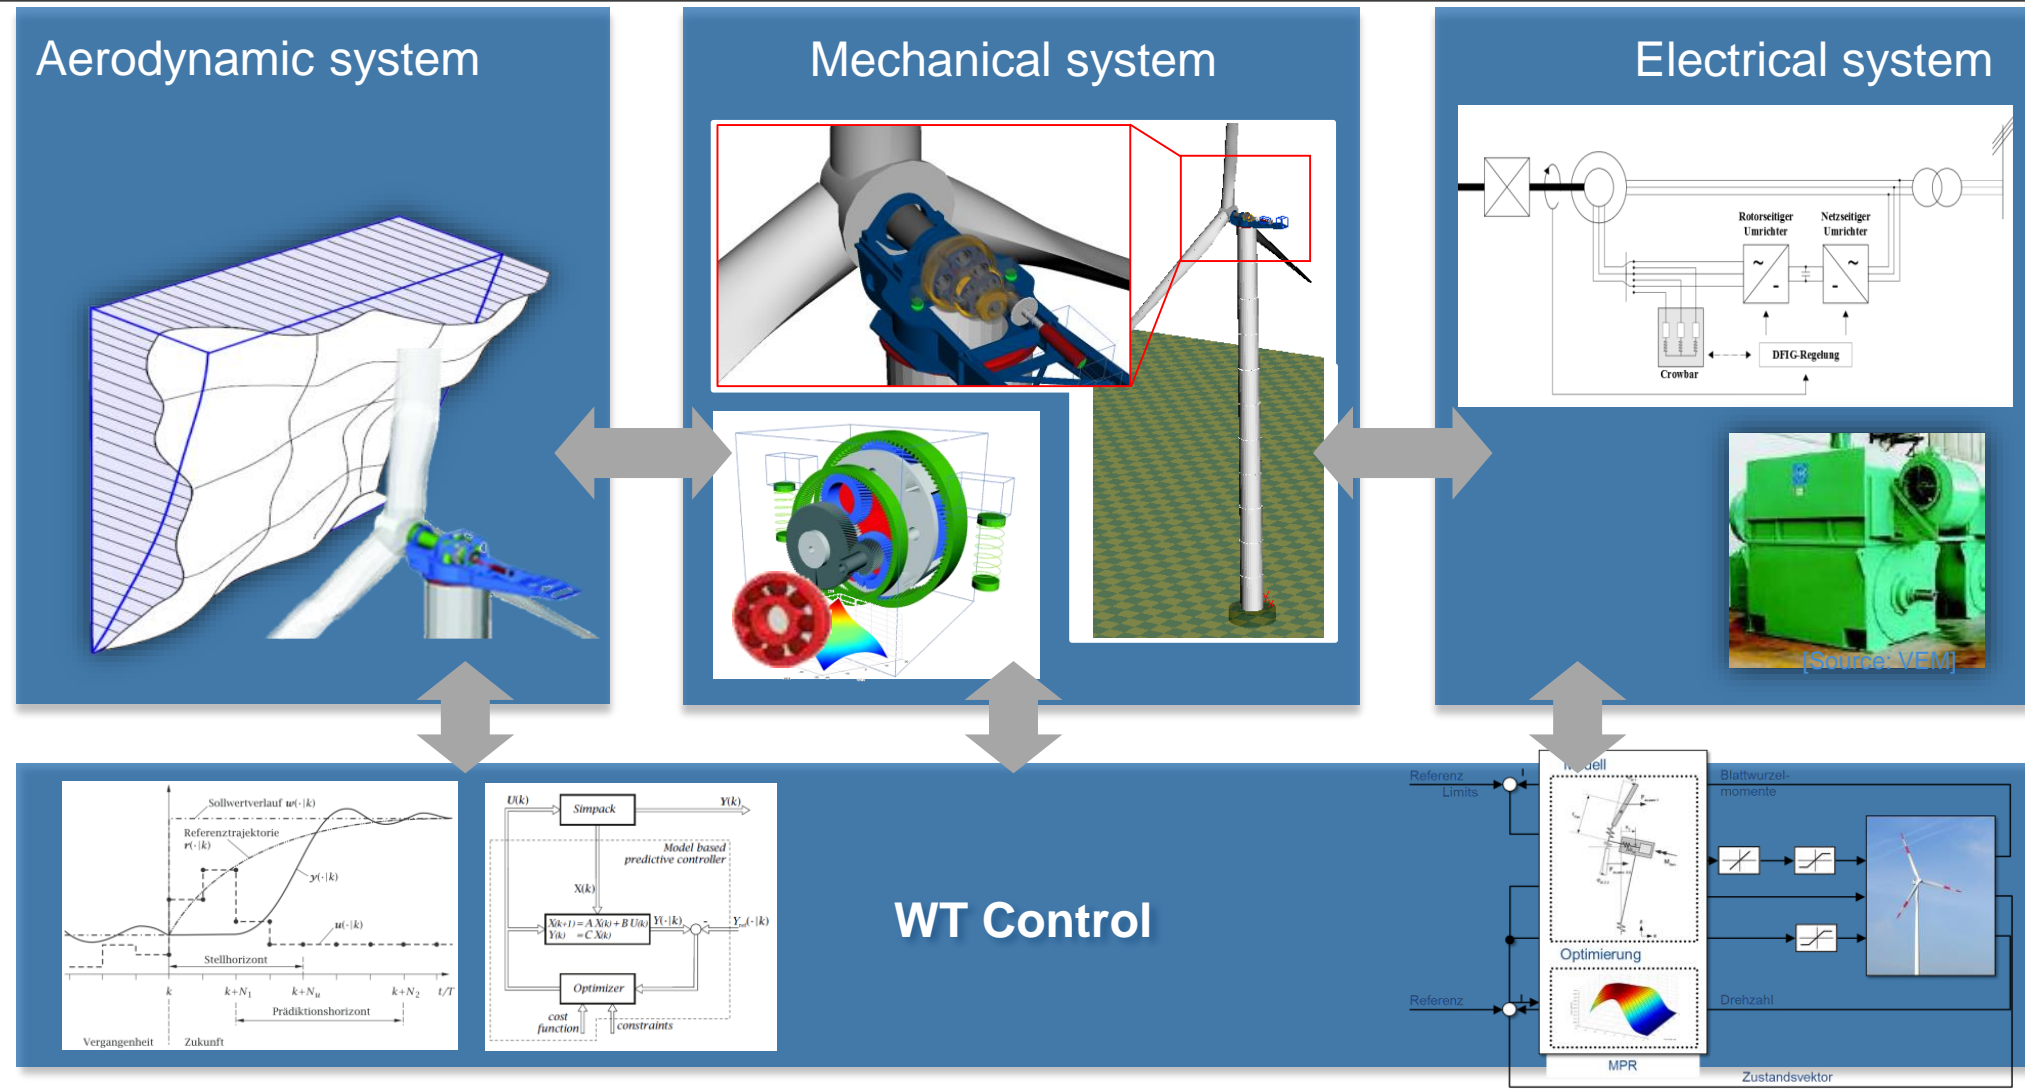

Load distribution based on SCADA using Mean Signal

Approach of the research project

Multi-body Simulation

From 10min Scada-data to 1s data

Normal Distribution – Method 1

- Input: SCADA 10min values
- Assumed values are normal distributed

$$f(x) = \frac{1}{\bar{\sigma} \cdot \sqrt{2\pi}} \cdot e^{-0.5 \cdot \left(\frac{x-x_{mean}}{\bar{\sigma}}\right)^2}$$

where: $\bar{\sigma} = \frac{\sigma_1 + \sigma_2}{2}$

- x_{mean} the mean value for 10min
- Assuming normal distribution
 - Standard deviation is mean of :
 - Min value at $-3 \cdot \sigma_1$
 - Max value at $3 \cdot \sigma_2$
- Redistributing the out of bounds probability along interval
- Sum of the area equals 1 for each 10min value interval

Assumed distribution

Redistributing

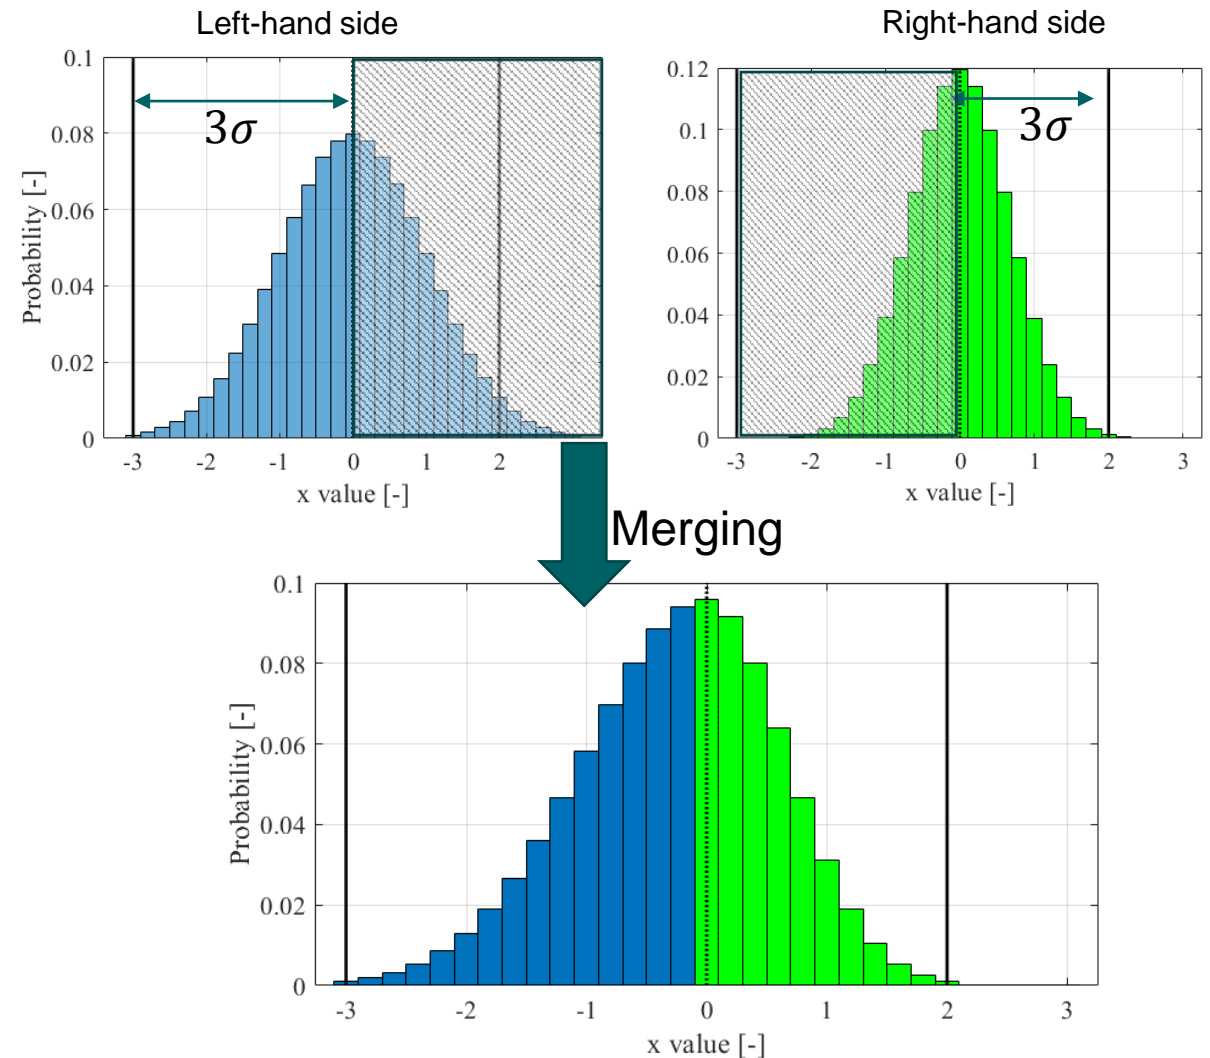

From 10min Scada-data to 1s data

Normal Distribution – Method 2

- Using two different normal distributions for left-/right-hand side of mean value

$$f(x) = \frac{1}{\sigma \cdot \sqrt{2\pi}} \cdot e^{-0.5 \cdot \left(\frac{(x-x_{mean})}{\sigma}\right)^2}$$

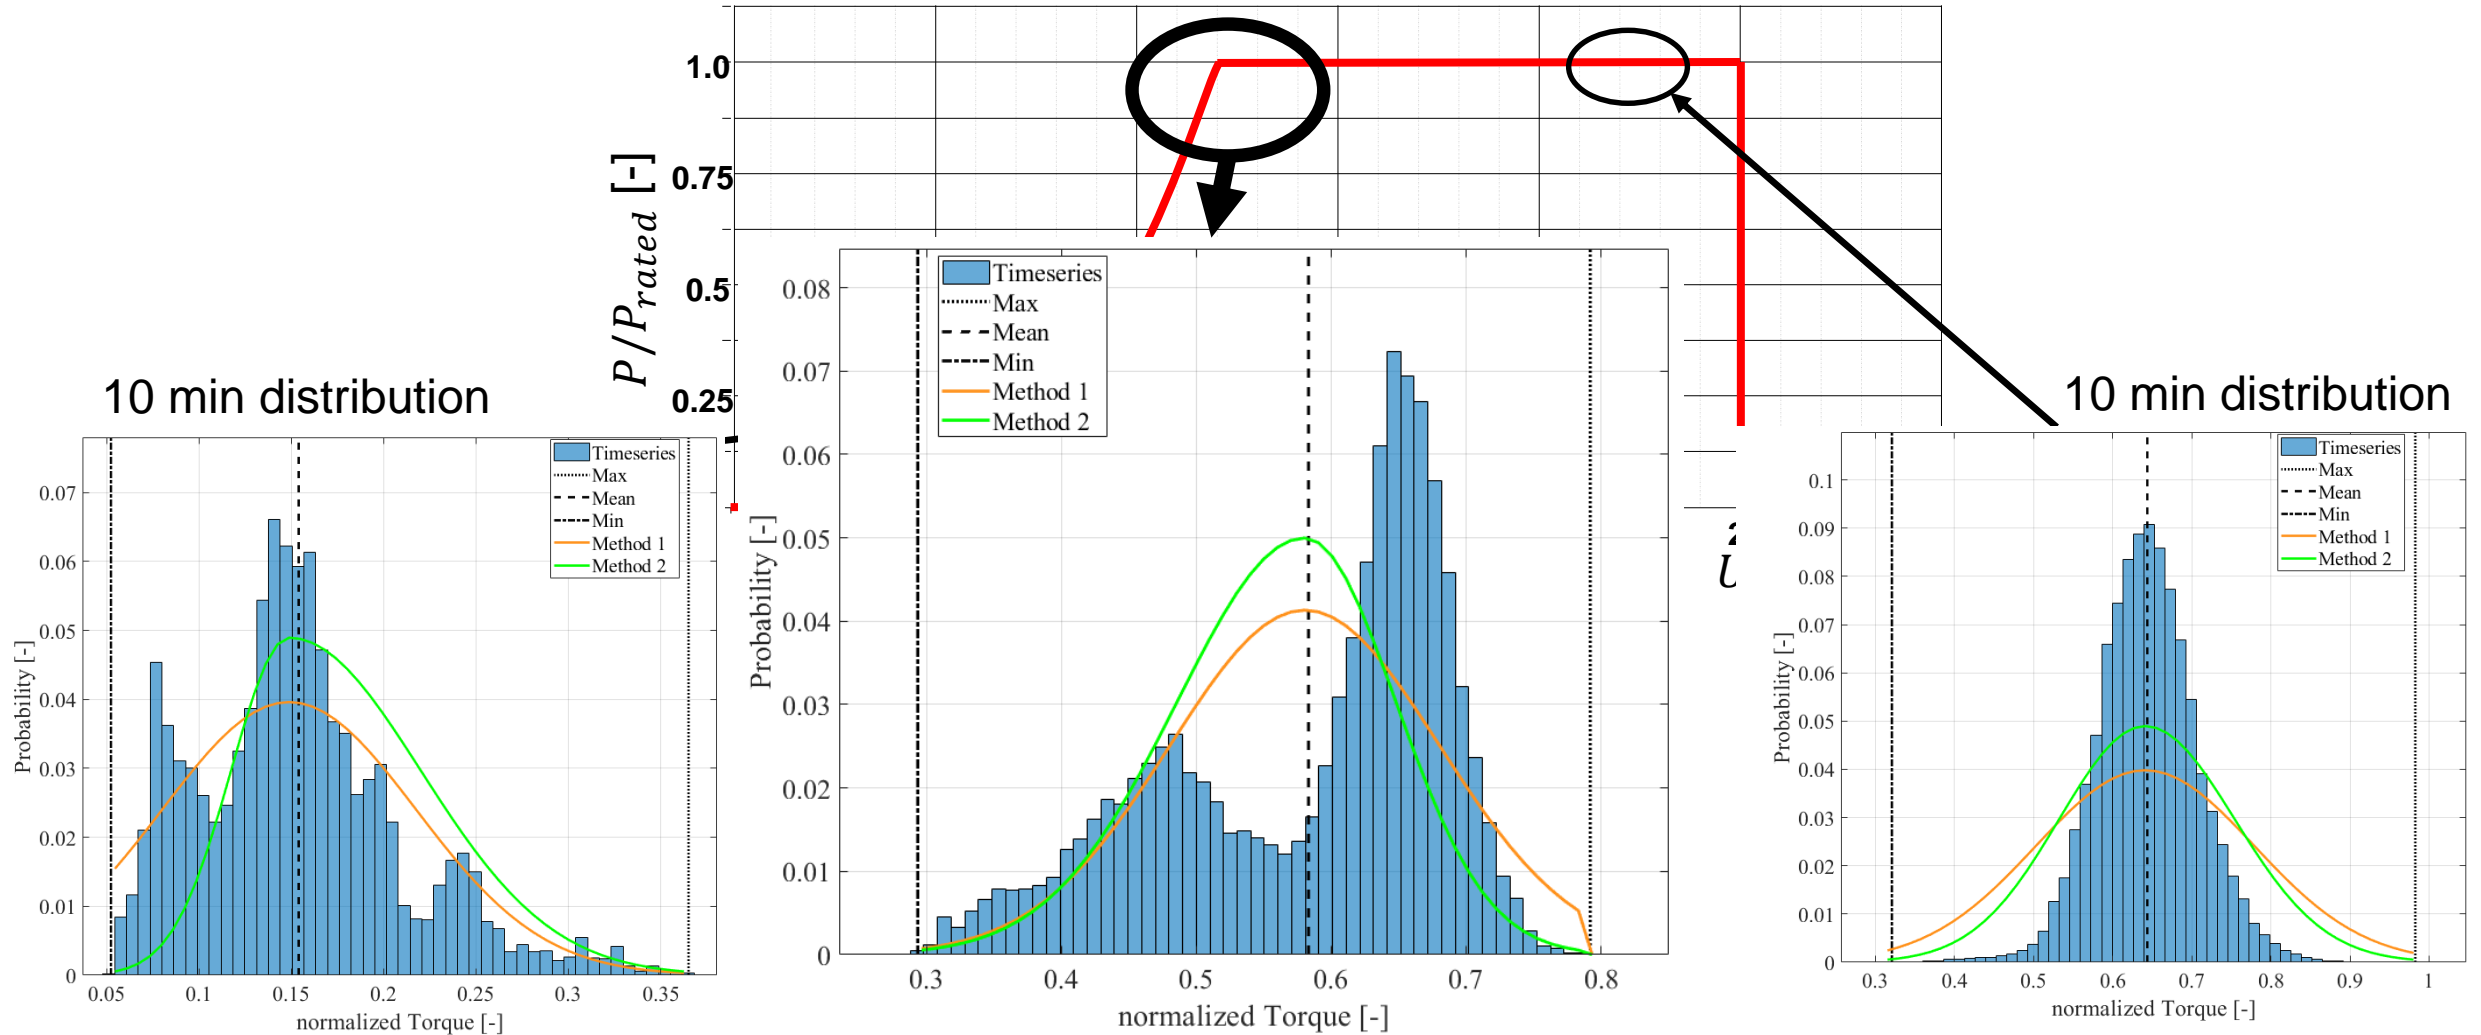

- Assuming max./min. value of 10min SCADA are at 3σ
→ Probability of max./min. value at 0.15%
- Merging distributions at mean
- Sum of the area equals probability of 1 for each 10min value interval

Distributions along Power Curve

Distributions along Power Curve

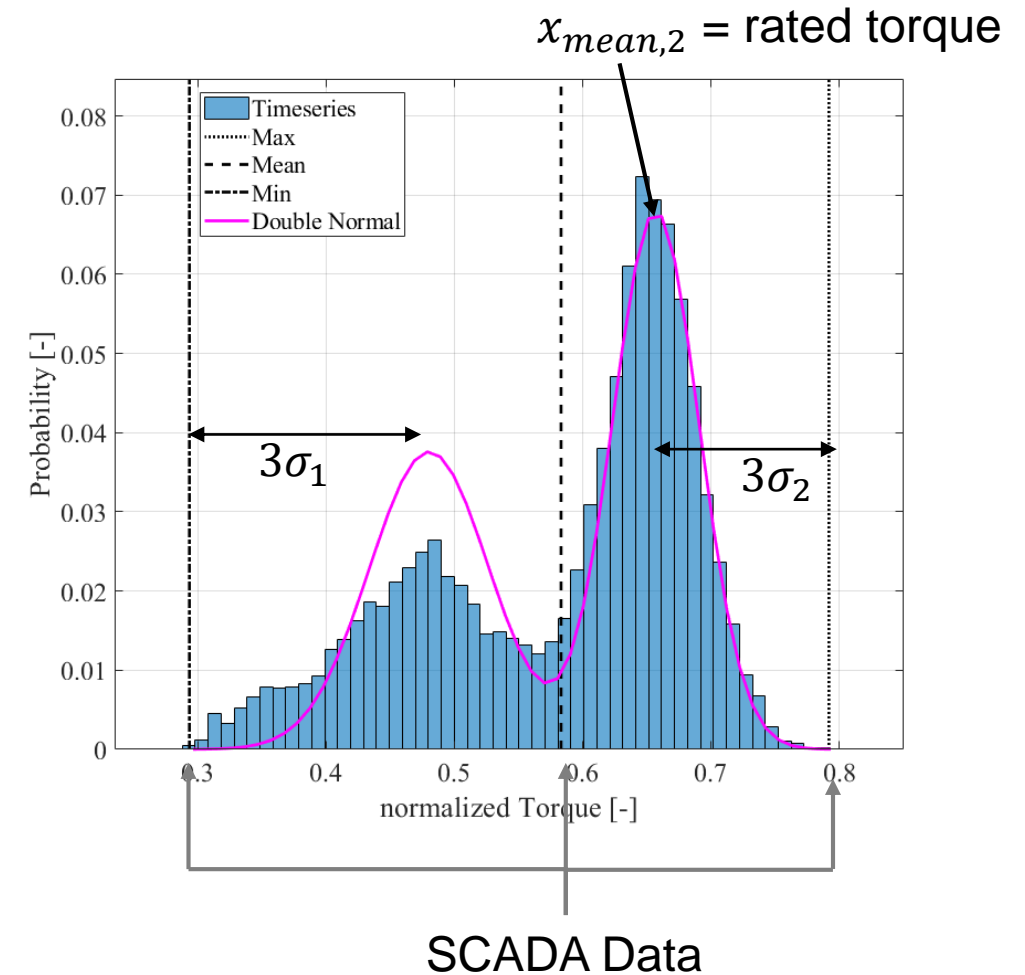

From 10min Scada-data to 1s data

Double Normal Distribution

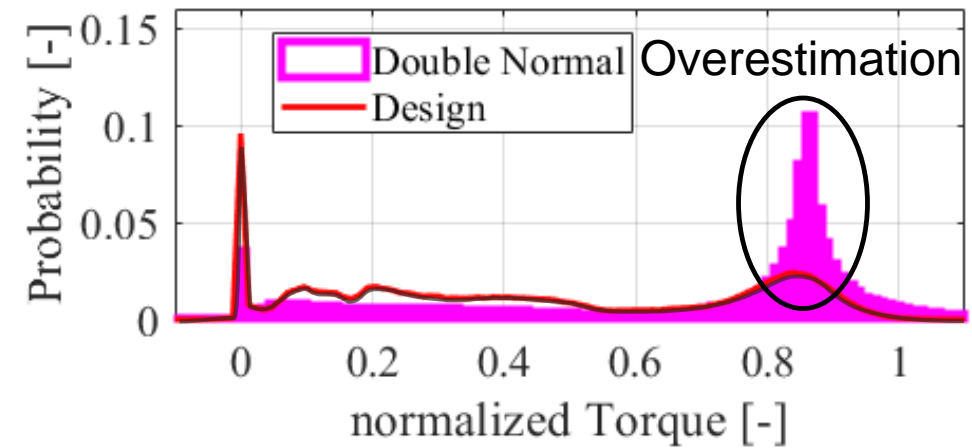

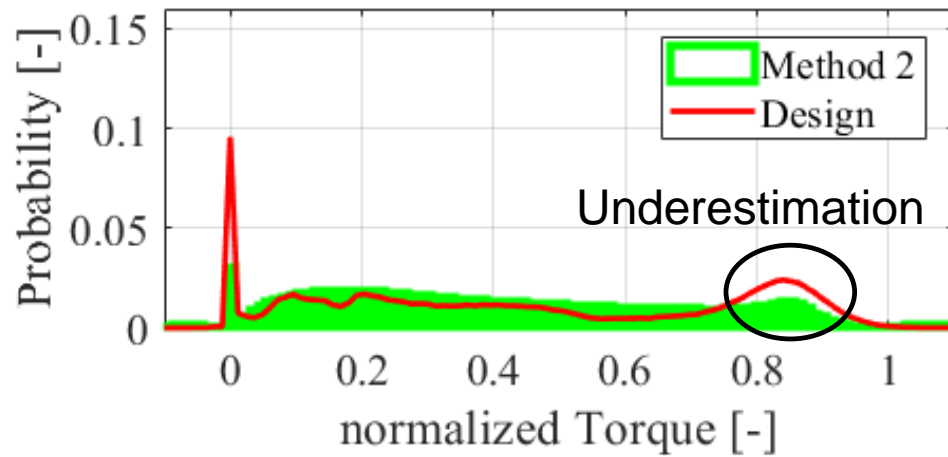

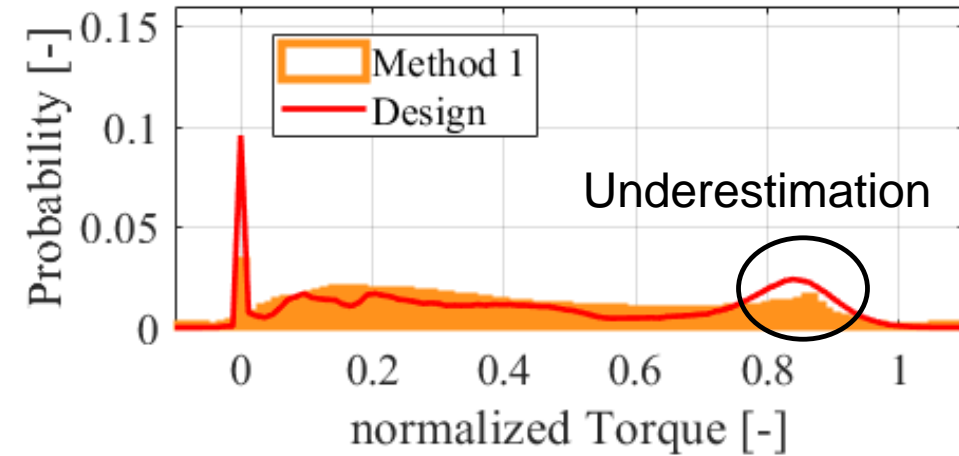

- The values within 10min are normal distributed

$$f(x) = (w) \cdot \frac{1}{\sigma_1 \cdot \sqrt{2\pi}} \cdot e^{-0.5 \cdot \left(\frac{(x-x_{mean,1})}{\sigma_1}\right)^2} + (1-w) \cdot \frac{1}{\sigma_2 \cdot \sqrt{2\pi}} \cdot e^{-0.5 \cdot \left(\frac{(x-x_{mean,2})}{\sigma_2}\right)^2}$$

- Using two different distributions for left-/right-hand side of mean value
- Assuming max./min. value of 10min SCADA are at 3σ of each normal distribution
- $x_{mean,2}$ at rated torque
- $x_{mean,1}$ determined iteratively
 - $x_{mean,1} < x_{mean,SCADA}$
 - Overall mean of distribution fits mean of SCADA
- Weighting w determined by SCADA Pitch signals

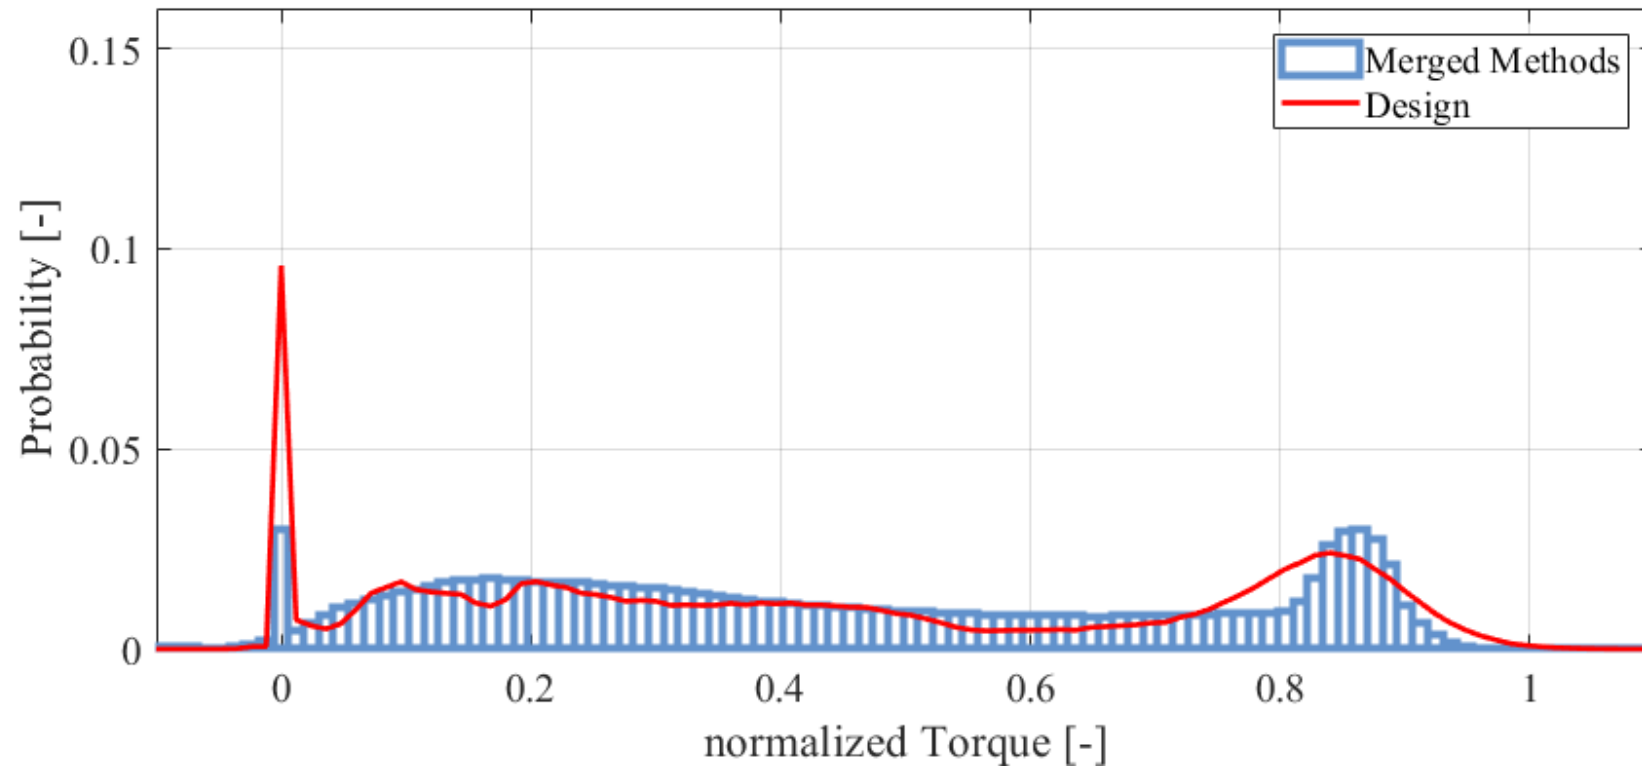

Resulting LDD per Method

Resulting LDD

Combination of Methods

- Combination of Methods along power curve
 - Below rated: Method 1
 - Above rated: Method 2
 - At rated: Double Normal Distribution

Conclusion

- 10 min SCADA data can be used to estimate a 1Hz distribution
- Above rated condition distribution similar to tilted normal distribution
- Below rated condition distribution widely spread
- At rated a double normal distribution required
- Combination of Methods based on operational status leads to results similar to design loads

Thank you for your attention.
